

Acnezine To Cure All Types Of Acne Lesions

Let us study the different types of acne that Acnezine can cure: Lesion-a physical change in body tissue caused by disease or injury. A lesion may be external (e.g., acne, skin cancer, psoriatic plaque, knife cut), or internal (e.g., lung cancer, atherosclerosis in a blood vessel, cirrhosis of the liver).

Acne lesions range in severity from comedones (blackheads and whiteheads) to nodules and cysts. Here is a brief definition of acne lesions:

Comedo (plural comedones)-A comedo is a sebaceous follicle plugged with sebum, dead cells from inside the sebaceous follicle, tiny hairs, and sometimes bacteria. When a comedo is open, it is commonly called a blackhead because the surface of the plug in the follicle has a blackish appearance. The antioxidant Acnezine regulates the sebaceous glands thus controlling the oil secretion and stops acne growth permanently. Neither blackheads nor whiteheads should be squeezed or picked open, unless extracted by a dermatologist under sterile conditions.

Papule-A papule is defined as a small (5 millimeters or less), solid lesion slightly elevated above the surface of the skin. A group of very small papules and microcomedones may be almost invisible but have "sandpaper" feel to the touch. A papule is caused by localized cellular reaction to the process of acne. Prolong treatment with Acnezine smoothes the lesion to a great extent.**Pustule**-a dome-shaped, fragile lesion containing pus that typically consists of a mixture of white blood cells, dead skin cells, and bacteria. A pustule that forms over a sebaceous follicle usually has a hair in the center. Acne pustules that heal without progressing to cystic form usually leave no scars.

Nodule-like a papule, a nodule is a solid, dome-shaped or irregularly shaped lesion. Unlike a papule, a nodule is characterized by inflammation, extends into deeper layers of the skin and may cause tissue destruction that results in scarring. A nodule may be very painful. **Nodular acne** is a severe form of acne that may not respond to therapies other than isotretinoin.

Cyst-a cyst is a sac-like lesion containing liquid or semi-liquid material consisting of white blood cells, dead cells, and bacteria. It is larger than a pustule, may be severely inflamed, extends into deeper layers of the skin, may be very painful, and can result in scarring. Cysts and nodules often occur together in a severe form of acne called nodulocystic.

Acnezine is the answer to all these acne lesions for it is a natural product with no side effects and guarantees positive result if treated for a considerable period of time.
